

P. HUEMER, C. MORANDINI

BIODIVERSITY OF LEPIDOPTERA WITHIN THE AREA OF VALLE VECCHIA
(CAORLE, VENEZIA) WITH SPECIAL REGARD TO
NATURE CONSERVATION ASPECTS

*CONTRIBUTO ALLA CONOSCENZA DEI LEPIDOTTERI DELL'AREA DI
VALLE VECCHIA (CAORLE, VENEZIA) CON PARTICOLARE RIGUARDO AGLI
ASPECTI CONSERVAZIONISTICI*

Abstract - 684 species of butterflies and moths are recorded from the area of Valle Vecchia (Caorle, Venezia). The species inventory includes two probably undescribed species: *Apatetris* sp. n. and a species of the Crambidae subfamily Odontiinae. 9 species are newly recorded from Italy: *Phyllonorycter cephalariae*, *Cosmiotes stabilella*, *Cosmopterix pararufella*, *Eulamprotes immaculatella*, *Scrobipalpa nitentella*, *Ephysteris insulella*, *Gynnidoromorpha luridana*, *Clavigesta purdeyi* and *Assara turciella*. Several species are extremely rare and/or scattered in Italy or even restricted to Valle Vecchia, e.g. *Xylomoia stangelmaieri*. The importance of the area is furthermore underlined by the occurrence of *Lycaena dispar* and *Euplagia quadripunctaria*, two species protected by the Fauna-Flora-Habitat directive of the EU. An ecological analysis underlines the particular importance of the sandy dune system and halophytic depression for Lepidoptera. Bed of reeds and hygrophilous to xerophilous grassland add to the overall diversity. Recent afforestations probably will improve the importance of woody plants. Biogeographically, species which are widely distributed in Eurasia and/or North America or which are even cosmopolitan cover about 72% of the inventory. Furthermore the European and Mediterranean chorotypes are of some importance with 17% and 4% respectively of the species inventory. Finally conservation problems and management are discussed in detail. Suggestions for habitat specific improvements are given.

Key words: Lepidoptera, Faunistics, Conservation, Dune Systems, Italy, Veneto.

Riassunto breve - Sono state rinvenute 684 specie di Lepidotteri nell'area di Valle Vecchia (Caorle, Venezia). L'elenco delle specie include due entità probabilmente non ancora descritte: *Apatetris* sp. n. e una specie della famiglia Crambidae, sottospecie *Odontiinae*. Nove specie rappresentano nuove segnalazioni per l'Italia: *Phyllonorycter cephalariae*, *Cosmiotes stabilella*, *Cosmopterix pararufella*, *Eulamprotes immaculatella*, *Scrobipalpa nitentella*, *Ephysteris insulella*, *Gynnidoromorpha luridana*, *Clavigesta purdeyi* e *Assara turciella*. Diverse specie sono estremamente rare o distribuite localmente a livello italiano, o anche limitate all'area di Valle Vecchia, come nel caso di *Xylomoia stangelmaieri*. L'importanza dell'area è inoltre sottolineata dalla presenza di *Lycaena dispar* e *Euplagia quadripunctaria*, due specie protette dalla Direttiva Comunitaria Habitat (Dir. 92/43 CEE). Un'analisi ecologica evidenzia la particolare importanza del sistema dunale e delle depressioni interdunali per i Lepidotteri. I canneti

e le praterie igrofile e xerofile aumentano la diversità complessiva ma sono relativamente meno ricchi di specie rispetto ad altri habitat. I recenti interventi di riforestazione aumenteranno probabilmente l'importanza delle piante forestali sotto il profilo ecologico. Dal punto di vista biogeografico, le specie ampiamente distribuite in Eurasia e/o in Nord America o a distribuzione cosmopolita coprono circa il 72% del totale. Anche i corotipi Europeo e Mediterraneo sono inoltre di rilievo, con rispettivamente il 17% e il 4% del totale. Sono discussi in dettaglio gli aspetti conservazionistici e vengono forniti suggerimenti per interventi migliorativi nei diversi habitat specifici.

Parole chiave: Lepidoptera, Faunistica, Conservazione, Italia, Veneto, Dune litorali.

Introduction

The upper Adriatic coast is nowadays mainly dominated by tourist infrastructure and agriculture and only few areas without strong anthropogenic impact have been conserved. One of the largest semi-natural dune areas of Veneto is found in Valle Vecchia (Caorle). Despite of the intensive agriculture in the northern and central parts of this area, the dune system remained nearly untouched with a high potential for the formerly widely distributed and site-characteristic fauna and flora. This situation was already documented for some groups of arthropods (GLEREAN, 2004).

However, the presumed decline of biodiversity in the area, following the pre-reclaiming during the 20th Century cannot be estimated in detail due to lack of earlier investigations both of fauna and flora along the formerly natural coasts. Similarly to other groups the fauna of Lepidoptera of the entire upper Adriatic area has been studied only very sporadically by few lepidopterists and published data are widely distributed through entomological journals and books. A major work about the Lepidoptera of the Adriatic islands dates back to GALVAGNI (1909) and many of its data may apply to other areas. Some unpublished material is preserved in private and institutional collections, e.g. the one of the Museo Friulano di Storia Naturale in Udine. Furthermore very interesting material was published during the last years, including three new species for science from the area of Valle Vecchia (LAŠTUVKA & LAŠTUVKA, 1997; MIKKOLA, 1998; HUEMER, 2002a) indicating a lepidopterological coenosis of particular value, concerning biogeography and faunistics but also for conservational aspects. A more detailed exploration of the lepidopterological communities within characteristic natural habitats of the upper Adriatic coast was therefore of high scientific and conservational interest.

Material and methods

The collecting methods were selected to enable a registration of a maximum amount of species within a limited number of excursions.

Due to the night activity of about 85% of central European Lepidoptera mainly light-trapping methods were chosen but also traditional sampling methods during day-time:

- illuminated white sheet (light source 125W UV)

- light tower (light source 15W-20W UV)
- usage of a dip net
- visual registration of day-active species
- visual registration of larvae and leaf-miners
- usage of bait (sugar-wine-vinegar mixture)

In general several of these methods were used simultaneously.

A large number of excursions were carried out during the vegetation periods from 1981 onwards with a focal point from the late 1990ties until 2005 by following specialists:

Dr. P. Huemer, Dr. C. Morandini, L. Morin, Mag. S. Ortner, G. Stangelmaier and Dr. C. Wieser.

Voucher specimens of most of the species are deposited in the collections of the Museo Friulano di Storia Naturale, Udine. Additional material is deposited in the collections of the Tiroler Landesmuseum Ferdinandeum, Innsbruck and in the private collections of some of the above mentioned specialists.

The variation in methodology and the - at least in earlier sampling years - insufficiently described site characteristics did not enable a detailed statistical analysis. However, the data proved sufficient for an ecological evaluation of the species inventory.

- Veduta aerea di Valle Vecchia (Caorle).

Results

Species inventory - biodiversity

The species inventory of the Valle Vecchia revealed 684 species of Lepidoptera belonging to 50 different families. The Lepidoptera communities can be regarded as representative for the relict dune systems of the upper Adriatic coast. The lepidopterological fauna includes numerous most remarkable taxa, many of them strongly restricted to habitats of the dunes and coastal area in general.

New faunistic records

The faunistic approach resulted in 9 new records for the Italian fauna and some additional species for the northern part of the country. Furthermore two additional species are probably still undescribed and new to science.

***Phyllonorycter cephalariae* (LHOMME, 1934) (Gracillariidae)**

General distribution: France, Croatia and Greece. New record for Italy!

Ecology: the larva is restricted to xerothermic habitats with stands of the hostplant *Scabiosa*. In Valle Vecchia *Scabiosa gramuntia* is the probable hostplant.

Records: Valle Vecchia, 08.06.2001, leg. Morandini.

***Cosmiotes stablella* (STAINTON, 1858) (Elachistidae)**

General distribution: widely distributed from north-western to central Europe, absent from the Balkans and parts of the Mediterranean area. New record for Italy!

Ecology: the larva mines the leaves of a number of Poaceae, e.g. *Avena* and *Agrostis*. The species is most frequently found in open xerothermic habitats.

Record: Valle Vecchia, 30.05.2003, leg. Morandini.

***Cosmopterix pararufella* RIEDL, 1976 (Cosmopterigidae)**

General distribution: southern Spain, Corsica, Cyprus and northern Africa. New record for Italy!

Ecology: the larva was found mining the leaves of sugarcane (*Saccharum officinarum*) but it certainly feeds on other Poaceae as well. The habitats are insufficiently known in Italy but the single adult was collected in the dunes.

Record: Valle Vecchia, 06.06.2005, leg. Huemer.

***Apatetris* sp. n. (Gelechiidae)**

General distribution: Italy and Corse. In Italy beside Valle Vecchia also recorded from Monfalcone (Gorizia). New species to science!

Ecology: hostplant and early stages unknown. This undescribed species seems to be restricted to halophytic habitats.

Remarks: the generic attribution is tentative and the species could belong to an undescribed genus.
Record: Valle Vecchia, 01.-10.06.2000, leg. Morandini.

***Eulamprotes immaculatella* (DOUGLAS, 1850) (Gelechiidae)**

General distribution: insufficiently known, presently recorded from Ireland to German and from the Iberian Peninsula to the Balearic Islands. New record for Italy!

Remarks: the biology of this species is nearly unknown.
Record: Valle Vecchia, 07.07.2004, leg. Huemer.

***Scrobipalpa monochromella* (CONSTANT, 1895) (Gelechiidae)**

General distribution: only known from southern France, Italy and Spain. New record for the northern part of Italy!

Ecology: the larva has been recorded from *Limonium vulgare* (Plumbaginaceae). It feeds between spun leaves or as a leaf-miner. The species is easily attracted to artificial light sources. *S. monochromella* is restricted to halophytic habitats in coastal areas.

Record: Valle Vecchia, 27.05.2005, leg. Morin.

***Scrobipalpa nitentella* (FUCHS, 1902) (Gelechiidae)**

General distribution: widely though locally distributed from Great Britain to Mongolia. New record for Italy!

Ecology: the larva feeds on various species of halophytic Chenopodiaceae such as *Sueda*, *Salicornia*, *Atriplex* and *Chenopodium*. *S. nitentella* is restricted to halophytic habitats, both on coasts and inland.

Record: Valle Vecchia, 06.08.2004, leg. Morin.

***Ephysteris insulella* (HEINEMANN, 1870) (Gelechiidae)**

General distribution: only known from widely scattered localities in the southern part of Central Europe and from southeastern Europe. New record for Northern Italy! Already collected by Fiori in Fano (Marche), Torrette, 17.VI.[1]953, A. Fiori (coll. Zoologische Staatssammlung, Munich) and by Deutsch in Karst near Lamiano (GO), 12.10.1999, det. P. Huemer (DEUTSCH, 2009).

Ecology: hostplant and early stages unknown. The species is only known from psammophytic habitats where it may feed on roots of Poaceae.

Records: Valle Vecchia, 15.06.1998, leg. Wieser; ditto, but 28.04.2004, leg. Morin; ditto, but 01.09.2000; ditto, but 07.07.2004, leg. Huemer.

***Stomopteryx hungaricella* GOZMÁNY, 1957 (Gelechiidae)**

General distribution: only recorded from isolated localities from eastern Central Europe and Sardinia; furthermore from Turkey. New record for Italian mainland!

Ecology: hostplant and early stages unknown. The larva most probably feed on Fabaceae as other members of the genus. *S. hungaricella* has only been recorded from xerophilous, steppic habitats so far.

Record: Valle Vecchia, 07.07.2004, leg. Huemer & Morin.

***Anarsia* sp. (Gelechiidae)**

General distribution: only known from Italy so far but possibly belonging to one out of the several

unrevised or insufficiently documented species described from France by REAL (1994)! Known from several localities of the Italian mainland.

Ecology: hostplant and early stages unknown. The adults have been collected on several occasions at light and they seem to occur in different forest habitats.

Records: Valle Vecchia, 30.05.2003, leg. Morin; ditto, but 07.07.2004, leg. Huemer & Morin; ditto, but 06.06.2005, leg. Huemer.

***Gynnidiomorpha luridana* (GREGSON, 1870) (Tortricidae)**

General distribution: scattered records from Great Britain to Scandinavia and France; furthermore recorded from the Russian Far East. New record for Italy!

Ecology: insufficiently known. The larva has been bred from the flower-heads of *Matricaria recutita* but considering the bivoltinism it may also feed on other parts of the host-plant.

Records: Valle Vecchia, 01.06.2002, leg. Morin; ditto, but 10.06.2004, leg. Wieser.

***Cnephasia conspersana* (DOUGLAS, 1850) (Tortricidae)**

General distribution: from the Iberian Peninsula and Great Britain to France, Italy and north-western Africa. New record for the northern part of Italy!

Ecology: the larva feeds on a large number of herbs and the species seems to prefer xerothermic habitats.

Record: Valle Vecchia, 03.06.2000, leg. Morin.

***Clavigesta purdeyi* (DURRANT, 1911) (Tortricidae)**

General distribution: Locally distributed from Great Britain to Central Europe. New record for Italy (HUEMER, MORANDINI & MORIN, 2005)!

Ecology: the larva has been found feeding on *Pinus*. Despite of the widely distributed hostplant *C. purdeyi* is a scattered and rare species.

Records: Valle Vecchia, 08.09.2000, 07.07.2004, 06.08.2004, leg. Morin.

***Acrobasis foroiliensis* HUEMER & NUSS, 2006 (Pyralidae)**

General distribution: only known from Northern Italy! Beside Valle Vecchia recorded from few Nature reserves in Friuli Venezia Giulia (HUEMER & NUSS, 2006).

Ecology: hostplant and early stages unknown, possibly related to hygrophilous shrubs. The adults have been collected in thermophilous wetland habitats at low altitude.

Record: Valle Vecchia, 27.08.2004, leg. Huemer.

***Metallostichodes nigrocyanella* (CONSTANT, 1865) (Pyralidae)**

General distribution: southernmost Europe and from Morocco to the Near East. New record for the northern part of Italy!

Ecology: hostplant and early stages insufficiently known. In Morocco the adult has been bred from the flowers of *Achras sapota* on a single occasion.

Record: Valle Vecchia, 03.08.2003, leg. Morandini.

***Assara turciella* ROESLER, 1973 (Pyralidae)**

General distribution: only known from Turkey so far. New record for Italy and Europe!

Ecology: hostplant and early stages unknown. The type-series has been collected in dunes along the southern coast of Turkey.

Records: Valle Vecchia, 06.08.2004, leg. Morin; ditto, but 07.07.2004, 21.09.2004 and 06.06.2005, leg. Huemer.

Hyperlais nemausalis (DUPONCHEL, 1834) (Pyralidae)

General distribution: Mediterranean area. New record for the northern part of Italy!

Ecology: hostplant and early stages unknown. The adults have been collected north of the pinewood in the interdunal depressions and the species seems to prefer xerophilous habitats.

Records: Valle Vecchia, 03.05.1998, 15.06.1998, 13.05.2000, leg. Wieser; ditto, but 06.06.1998, 04.06.1999, 07.06.1999, 03.06.2000, 05.06.2000, 26.05.2001, 01.06.2002 and 30.05.2003, leg. Morin; ditto, but 01.-10.06.2000 and 03.08.2003, leg. Morandini; ditto, but 07.07.2004, leg. Huemer.

Odontiinae gen. sp. (Pyralidae)

General distribution: New record for Italy and Europe! Possibly new to science!

Ecology: hostplant and early stages unknown.

Remarks: a member of the subfamily Odontiinae which, however, cannot be identified even to generic level at the moment. The species is new to Europe and may be undescribed. Probably a further specimen from Greece is conspecific (Speidel in litt.).

Record: Valle Vecchia, 07.06.1999, leg. Morin.

Regionally rare and/or endangered species

Beside of new national or regional records a high number of species observed in the area of Valle Vecchia is rare and/or increasingly threatened throughout the region of Veneto and partially in entire Italy. This group of species is particularly important from a conservational point of view and includes several taxa from halophytic habitats with some of the most important and striking records of Lepidoptera for the area. Particularly *Xylomoia stangelmaieri* has to be considered with due care since this species has its only known locality in a worldwide sense in Valle Vecchia. Furthermore *Agdistis morini* and *Eucosma gradensis* are interesting with only very few additional localities along the upper Adriatic coast. Numerous hygrophilous species have become increasingly rare during the last decades throughout Central Europe, among them *Cosmopterix lienigiella* and *Monochroa palustrella* which are only known from very few localities in northern Italy. Furthermore a high number of locally distributed species were observed, e.g. *Pyroderces klimeschi*, *Celypha doubledayana*, *Chilo luteellus*, *Scirpophaga praelata*, *Nascia ciliaris*, *Scopula corrivalaria*, *Macrochilo cribrumalis*, *Simyra albovenosa*, *Eucarta amethystina*, *Mythimna flammea* and *Spilosoma urticae*. Species of the xerothermic

ecotype are in general more widely distributed and less endangered in Italy due to favourable climatic conditions. However, also this ecological group is well represented and includes very interesting and rare species such as *Eucosma flavispectula*, *Stenoptilia mariaeluisae*, *Oxybia transversella*, *Crambus hamella*, *Microloxia herbaria*, *Eublemma purpurina*, *Cucullia xeranthemi*, *Luperina dumerilii* and *Ochropleura leucogaster*.

Species protected by the Fauna-Flora-Habitat directive of the EU

The habitats represented in Valle Vecchia are only of limited importance for species protected by Annex 2 and/or 4 of the Fauna-Flora-Habitat directive of the EU. Two species, viz. *Lycaena dispar* (Lycaenidae) and *Euplagia quadripunctaria* (Arctiidae), could be observed.

***Lycaena dispar* (HAWORTH, 1803)**

General distribution: scattered records from France to northern Turkey.

Regional distribution: local records mainly from the Po plain, extending to Central Italy in the South.

Ecology: characteristic species of wetland habitats which occurs in meadows and along ditch-systems. The single specimen was observed in the western part of Valle Vecchia, north of the pinewood on a meadow joining a channel. *L. dispar* is probably more widely distributed in this kind of habitat. The larva feeds on *Rumex hydrolaphathum*, *R. obtusifolius* and *R. crispus*.

Remarks: protected by Annex 2 and 4 of the Fauna-Flora-Habitat directive of the EU.

Record: Valle Vecchia, 20.09.2004 (1 specimen), obs. Huemer, Morandini & Morin.

***Euplagia quadripunctaria* (PODA, 1761)**

General distribution: widely distributed throughout the Western Palaearctic region.

Regional distribution: local records from several regions of Italy.

Ecology: inhabiting a wide range of different habitats, though preferring humid ecotones. The adults are both nocturnal and diurnal. During the day they can be found on various plants, especially *Eupatorium cannabinum*. In search for nectar source plants they fly considerable distances of up to about 300 m. The larva feeds on a large variety of host-plants, including *Lonicera xylosteum*, *Salix* spp., *Quercus* spp., *Epilobium* spp., *Plantago* spp. and *Lamium* spp.

Remarks: protected by Annex 2 und 4 of the Fauna-Flora-Habitat directive of the EU. Species of priority interest!

Record: Valle Vecchia, 01.09.2005 (1 specimen), obs. Morandini.

Ecological aspects

The methodology used for this study is mainly based on irregular light trapping of nocturnal moths and additional search of diurnal species of Lepidoptera. Consequently most of the observed material is based on the adults which can fly actively over more or less considerable distances. The actual larval habitats cannot be assessed from these records alone. However, the autecology of pre-imaginal stages is rather well known for a major portion of Central European Lepidoptera and therefore it is possible to attribute species to ecological guilds and furthermore to habitats in most cases.

Ecological guilds

The linkage of species to micro-habitats is a difficult task which needs a lot of field-experience. Due to the considerable mobility of many species in the adult stage it is not meaningful simply to assign species to the site where they have been observed. The overall species diversity of the various biotopes was primarily concluded from the autecology of single species (ecological guilds - host-plants).

The determination and definition of ecological guilds is defined in the following way:

- | | |
|--|------------------------------|
| 1. hygwl - hygrophilous species of woodless landscape. | Attributed species: 73 spp. |
| 2. hal - halophytic species. | Attributed species: 29 spp. |
| 3. meswl - mesophilous species of woodless landscape. | Attributed species: 92 spp. |
| 4. mesec - mesophilous species of ecotones. | Attributed species: 63 spp. |
| 5. mesfo - mesophilous species of forest habitats. | Attributed species: 138 spp. |
| 6. xerwl - xerophilous species of woodless landscape. | Attributed species: 192 spp. |
| 7. xersh - xerophilous species of afforested habitats. | Attributed species: 39 spp. |
| 8. ubiq - ubiquitous species. | Attributed species: 55 spp. |

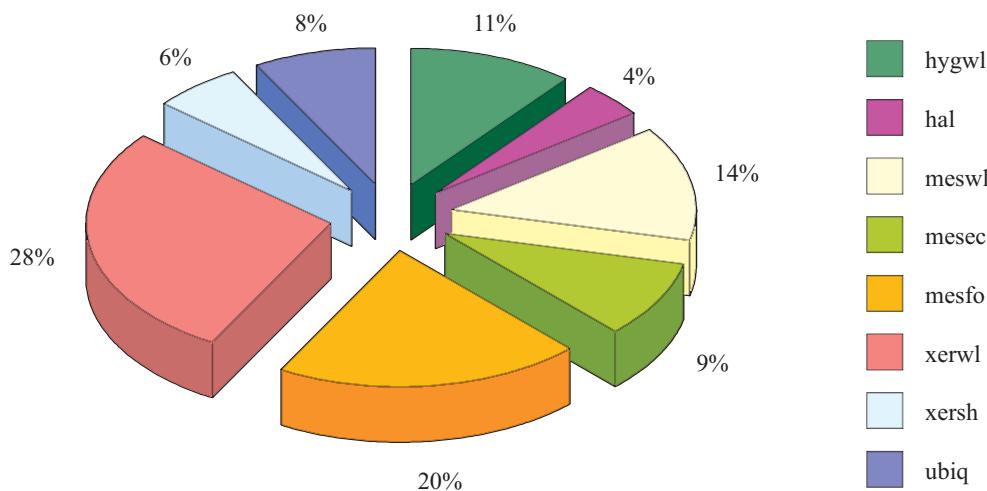

Fig. 2 - Percentage of species per ecological guild (all sites summarized). Hygwl = hygrophilous species of woodless landscape; hal = halophytic species; meswl = mesophilous species of woodless landscape; mesec = mesophilous species of ecotones; mesfo = mesophilous species of forest habitats; xerwl = xerophilous species of woodless landscape; xersh = xerophilous species of afforested habitats; ubiq = ubiquitous species.

- Percentuale di specie per ecotipo (tutti i siti complessivamente). Hygwl = specie igrofile di aree boscate; hal = specie allofitiche; meswl = specie mesofile di aree boscate; mesec = specie mesofile ecotonali; mesfo = specie mesofile di habitat forestali; xerwl = specie xerofile di aree boscate; xersh = specie xerofile di habitat forestali; ubiq = specie ubiquiste.

A major portion of the species diversity originates from open habitats without afforestation (fig. 2). Particularly xerophilous species of woodless landscape are of high importance with about 28% of the observed diversity. Furthermore 14% of the fauna is attributed to mesophilous species of woodless landscape, further 11% to hygrophilous woodless habitats and 4% to the halophytic ecotype. About 35% of the lepidopterous fauna of Valle Vecchia is related to afforested habitats, 6% out of this portion is regarded as xerophilous. Finally the ubiquitous species are exceptionally rich with 8% of the entire fauna, most of them related to openland habitats.

Species diversity of characteristic habitats

Sandy dune system

The sandy dune system is inhabited by a characteristic set of species. However, Lepidoptera are primarily occurring just in the advanced stage of the dunes with some vegetation. Most of the species developing in this kind of habitat are xerophilous species of woodless landscape or hygrophilous species. The xerophilous species include several taxa which are feeding on Poaceae and Cyperaceae such as all members of Elachistidae, probably *Ephysteris insulella* which is a new record for Italy, *Agriphila latistria* and a number of Noctuidae including the rare *Euxoa segnilis* which as other species of the latter family also develops on various herbs. The habitat of a further new country record, viz. *Cosmopterix pararufella*, is insufficiently known and this species may also develop in the more humid interdunal depressions.

The areas covered with a layer of moss are inhabited by *Bryotropha figulella* with its northernmost distribution limit in Italy and other species of *Bryotropha*. In the open dunes numerous several xerophilous herbs are growing, again with a characteristic and species-rich set of taxa such as the new Italian record of *Phyllonorycter cephalariae*, *Eulamprotes wilkella* from *Cerastium*, *Cochylimorpha woliniana*, *Aethes bilbaensis*, *Stenoptilia mariaeluisae*, *Oxybia transversella*, *Malacosoma castrensis*, *Microloxia herbaria*, *Idaea sylvestraria*, *Eublemma purpurina*, *Hadena irregularis* and many others. Probably also *Assara turciella* which is firstly recorded from Europe develops in this part of the dunes.

A site characteristic shrub of higher importance for Lepidoptera is *Tamarix gallica*. This plant is the exclusive host for five species: *Merulempista cingillella*, *Agdistis tamaricis*, *Eupithecia ultimaria*, *Godonella aestimaria* and *Clytie illunaris*. Since the hostplant only grows along coasts it is of specific interest. Further rare species are related to hygrophilous shrubs such as *Populus* and *Salix*, including several specialists such as *Earias vernana* from *Populus alba* or *Parastichtis ypsilon* which primarily feeds on older trees of *Populus nigra*.

Fig. 3 - The humid interdune depression and, in the background, the pine-wood (photo by P. Glerean).
- La depressione interdunale umida e, sullo sfondo, la pineta (foto di P. Glerean).

Fig. 4 - The open dune areas (photo by P. Glerean).
- Le aree aperte dunali (foto di P. Glerean).

The primary dune with sparse vegetation is typical for several ubiquitous and frequently also migrating species.

Halophytic depressions

Halophytic vegetation is restricted to interdunal depressions, particularly well developed in the southeastern part of Valle Vecchia. The vegetation is rather poor in species composition, dominated by *Limonium*, *Salicornia* and some other halophytes. However, despite of the low species diversity of altogether 28 halophytic taxa, the lepidopterological community is outstanding and includes numerous faunistically important lepidoptera. The species restricted to *Limonium* include two taxa which have been described from Valle Vecchia, *Acalyptris maritimella* and *Agdistis morini* (HUEMER, 2002a; LAŠTUVKA & LAŠTUVKA, 1997), and 4 further monophagous species, among which *Scrobipalpa monochromella* is firstly recorded for the northern part of Italy. A further interesting new country record which is restricted to halophytic Chenopodiaceae is *Scrobipalpa nitentella*. Some other species regarded as halophytic, e.g. those feeding on *Tamarix*, are here attributed to sandy dune systems.

At the top end of the salt marshes within the interdunal depressions stands of *Bolboschoenus maritimus* and *Juncus maritimus* are characteristic, again with some monophagous faunal elements such as *Coleophora maritimella* and *Monochroa moyses*. The local endemic *Xylomoia stangelmaieri* seems to prefer psammophytic habitats with stands of the probable host-plant *Erianthus ravennae*. *Agrotis syricola* is a further remarkable halophytic species first recorded as new for northern Italy from Valle Vecchia by ORTNER (2004). Within less halophytic humid habitats a large number of interesting hygrophilous species has been recorded, among them rare taxa such as *Simyra albovenosa*, several species of *Mythimna*, *Monochroa palustrella* which has just been published new to Italy (HUEMER, MORANDINI & MORIN, 2005), *Chilo luteellus*, *Scirphophaga praelata*, *Sclerocona acutella*, *Scopula corrivalaria* and many others. However, several of these species are also occurring in humid meadows north of the pinewood or even in the Phragmitetum.

Mixed pinewood

On the higher, stabilized dunes afforested stands of *Pinus pinea* but also *Pinus pinaster* and *P. nigra* are dominating. The species diversity of Lepidoptera within the closed mixed pinewood is very low due to the extremely limited resources of hostplants. Only few species are potentially feeding on Pinaceae, though *Clavigesta purdeyi* is a new addition to the Italian fauna. Furthermore *Decantha borkhausenii* which feeds under the dead bark of *Pinus* and *Picea* has been published as new to Italy only very recently (HUEMER, 2002b). Particularly the extremely poor herb layer is responsible for the low ecological

value of the Pinetum. Very few species such as *Millieria dolosalis* from *Aristolochia* and a few common taxa from *Rubus* are typical. The margins of the pinewood are richer in species since they are covered by some thermophilous shrubs such as *Crataegus* and *Ulmus*. A number of leaf-miners from the families Nepticulidae, Bucculatricidae and Gracillariidae are restricted to this habitat. Probably further thermophilous species are originating from this habitat.

Bed of reeds

Phragmites and *Typha* are dominating some parts north of the pinewood, partially over large areas, but also along the channel system. Furthermore *Phragmites* is also represented in interdunal depressions. The species number restricted to this kind of habitat is moderately low but adds to the overall species diversity due to a particularly specialized fauna. A number of species feeds exclusively on *Phragmites*, e.g. *Phragmataecia castaneae*, *Cosmopterix scribaiella*, *Cosmopterix lienigiella*, *Mythimna obsoleta*, *Mythimna flammea*, *Rhizedra lutosa* and *Chilodes maritima*. *Typha* is only used as an exclusive hostplant by *Limnaecia phragmitella* and *Calamatropha paludella*. Other species restricted to bed of reeds and the ditch systems are *Schoenobius gigantella*, *Nonagria typhae*, *Archana neurica* and *Archana sparganii*. Many of the species from reed live endophagous in the stems of the hostplant.

Uncultivated or extensively used hygrophilous to xerophilous grassland

Humid and dryer, mostly uncultivated or extensively used meadows are found along the embankments and in the northern part of the pinewood. They are important habitats for a majority of the butterflies occurring in the area but also for a large number of hygrophilous to xerophilous species of grassland. However, a similar species composition partially occurs in the dunes as well. The humid meadows are habitats of the EU protected *Lycaena dispar* which was observed in the north-western part of Valle Vecchia. However, this species may also develop along the channel system. The humid meadows are inhabited by interesting species such as *Monochroa palustrella*, *Clepsis spectrana*, *Eucarta amethystina*, *Deltote bankiana* and *Chariaspilates formosaria*. Xerophilous species such as *Eucosma flavispecula*, *Carcharodus alceae*, *Emmelia trabealis*, *Cucullia xeranthemi* and *Luperina dumerilii* may occur south of the pinewood in the dunes as well.

An ecologically remarkable group of species, feeding submersely under the water surface in the larval stage is restricted to rivulets and ponds of fresh water. Such species belong to the primarily tropical subfamily Acentropinae which is represented by 2 taxa: *Acentria ephemarella* and *Parapoynx stratiotata*.

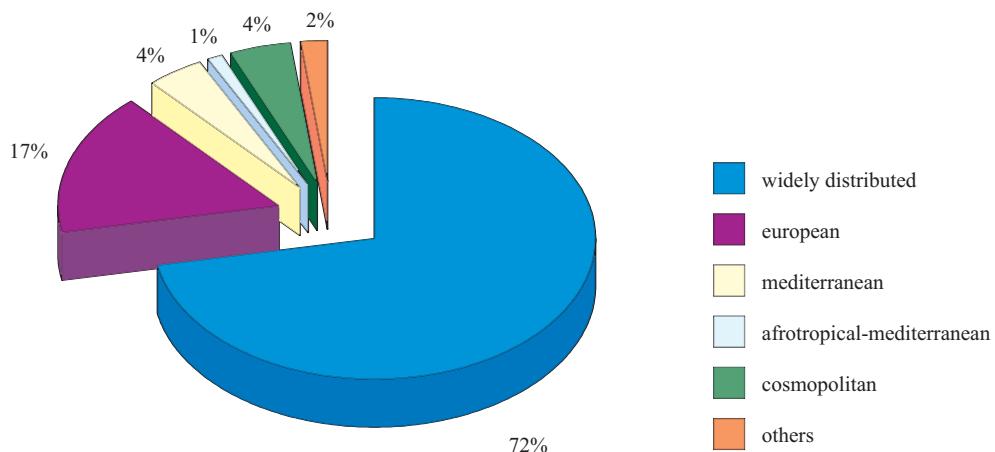

Fig. 5 - Percentage of major chorological categories (all sites added up).
- Percentuale delle principali categorie corologiche (tutti i siti complessivamente).

Biogeographical aspects

A biogeographic analysis on a larger geographic scale (fig. 5, species-checklist) proves the importance of species which are widely distributed in the Holarctic and/or Palearctic region (altogether 72%). However, only 46 species are holarctic (including Neobiota). Species with a wide Eurasian or palearctic distribution offer the highest diversity with altogether 189 species. 38 western palearctic species and 59 European-Siberian distribution are of further significance. The faunistic importance of the European chorological group with altogether 17% of the species inventory is obvious. This group also includes the few probably Italian endemic species, namely *Eucosma gradensis*, *Agdistis morini*, *Acrobasis foroiuliensis*, *Chortodes sohnretheli* and *Xylomoia stangelmaieri*. A further important chorological group are the 28 Mediterranean species which is about 4% of the species inventory, about the same species diversity as the 29 cosmopolitan or subcosmopolitan species. Afrotropical-Mediterranean species add to the overall diversity only in a very limited number of 8 species. The chorology of a moderately large number of species is still insufficiently known (2% of the fauna).

Habitat conservation and management

The conservation of a site-specific set of habitats is regarded as crucial for a long-term survival of characteristic and rare species. Numerous initiatives have been undertaken by Veneto Agricoltura during the last years for environmental requalification and renaturalization of the area. These measures included reflooding of humid-areas, afforestations, improvement

of the pinewood etc. However, large part of Valle Vecchia is still intensively used experimental farmland which is of marginal importance for Lepidoptera.

Dune system

The dune system is of extraordinary importance for the fauna of Lepidoptera with a high portion of the particularly valuable records which are mostly associated with the consolidated dunes. The conservation stage of the yellow and consolidated dune is rather satisfying at the moment and only local and limited anthropogenic influence based on various touristic activities is to be observed. However, it will be most crucial to avoid any tourist infrastructure within the dunes itself. The management of tourism and its limitation with creation of parking space, lavatories, refuse bins etc. in ecologically less sensitive areas outside of the dunes and the guidance of visitors within a strictly limited part of the dunes is most important. Such measures have been already started. The conservation of dunes will be supported by the strict ban of driving both along the driveway in the north and certainly within the pine forest and the dunes itself. Even naturalistic paths should be restricted to a few areas only.

Halophytic depressions

The conservation stage of halophytic depressions is rather satisfying and the touristic pressure on such a type of habitat is moderately low compared to the sandy dune system. However, foot paths through the depressions should be avoided and closed, and visitors should be guided only along the edge of the pinewood and the halophytic depressions, since the vegetation (and accordingly its Lepidoptera) is very sensitive towards any anthropogenic influence.

Mixed pinewood

The mixed pinewood can be regarded as an anthropogenic type of habitat in the area of Valle Vecchia. Its ecological value for species diversity of Lepidoptera is limited, due to the monotonous vegetation. To increase the value for this group a substitute afforestation with thermophilous deciduous trees such as oaks is recommended, at least in some parts of the pinewood. Furthermore plantations of hedgerows along the driveway in the northern part of the pinewood would add to the diversity. It may also be recommendable to create some open, non-shaded spots within the mixed pinewood for enhancement of the ecological situation of herbs and its Lepidoptera communities.

Artificially planted hygrophilous woodland

The recent plantations of mainly hygrophilous woody plants have not been investigated separately. However, the potential of such woodland for increasing local biodiversity is high, due to a large amount of species feeding primarily or exclusively on deciduous trees and shrubs.

However, the afforestation of natural or semi-natural habitats should be strictly avoided and plantation should be limited to habitats with a high anthropogenic impact such as intensively used agricultural areas.

Bed of reeds

Despite of its rather monotonous vegetation this habitat type is of high importance for some rare species. The conservations stage of bed of reeds is satisfactory at the moment since large areas are uncultivated. This is of particular importance since several of the characteristic Lepidoptera feed endophagous in the stems or in the seeds (e.g. *Typha*). Some species such as *Phragmataecia castaneae* are feeding and hibernating in the lower parts of the stem and consequently they are weakly sensitive towards moving of reed. Others such as *Chilodes maritima* or *Simyra albovenosa* feed in the higher parts of the stem and can only survive in uncultivated bed of reeds (HUEMER, 1996). It is therefore particularly important to leave parts of the bed of reeds untouched during the whole year.

Hygrophilous to xerophilous grassland

Embankment and parts of the area north of the mixed pinewood are uncultivated or extensively used, with dominating grassland of varying humidity, ranging from xerophilous to hygrophilous meadows. The flower-rich xerophilous grassland is important for the butterflies which are mainly found in the northern part of the dune system. They should not be mown during the main vegetation period from May to September. The species composition of mesophilous to hygrophilous grassland is pending on the stage of cultivation. The present anthropogenic influence is limited and several meadows are uncultivated. In other areas a temporally and spatially differentiated mowing or in general a certain variation of extensive cultivation will be useful for conservational purpose.

Manoscritto pervenuto il 20.VI.2008 e approvato il 25.XI.2008.

Acknowledgements

We are most grateful to several colleagues who have provided us data and partially material from Valle Vecchia over the last years, namely Lucio Morin (Monfalcone), Mag. Siegfried Ortner (Bad Ischl), Günther Stanglmaier (Villach) and Dr. Christian Wieser (Klagenfurt). Important help during field work and particularly technical assistance throughout the preparation of this work was provided by Dr. Paolo Glerean and Dr. Maria Manuela Giovannelli (both Museo Friulano di Storia Naturale, Udine).

The work was kindly supported by Veneto Agricoltura, Azienda Regionale per i settori Agricolo, Forestale e Agro-Alimentare.

Appendix

In the following table is reported the checklist of species, the chorological categories and the ecological aspects of Lepidoptera registered in Valle Vecchia (Caorle).

Legenda

Taxon

Systematic arrangement of families, genera and species, mainly follows KARSHOLT & RAZOWSKI (1996) with major adaptations of Fauna Europaea (www.faunaeuropaea.org).

Chorology (=Chor)

Chorotype (according to VIGNA TAGLIANTI et al., 1992); chorotypes of so called “macrolepidoptera” largely follow HELLMANN & BERTACCINI (2004).
